

ZeroInfra Labs Manual

Welcome

Welcome to the first hacking simulator that runs right in your browser!

This short guide explains the basic features of the simulator. Let's take a look at the tools you'll use during your missions.

1. The desktop

When you enter any lab, a Kali Linux-style desktop loads with:

- Terminal (>_ icon): your main console, always open when you start.
- Manual (PDF document icon): this guide, open alongside the terminal.
- Wallpapers (image icon): opens the wallpaper picker.
- Chrome (browser icon): only appears in web labs, to interact with the vulnerable applications.

On the top bar (taskbar) you have:

- The Applications menu (K letter) with quick access to Terminal, Change Wallpaper, View Manual, and Chrome.
- Buttons for all open windows (click to minimize, restore, or bring to front).
- The clock, the network status, and the power off button to exit the lab.

All windows can be moved (by dragging the title bar) and resized: drag the edges (top, bottom, left, or right) or the corners to adjust the size. You can also minimize, maximize, and close them from the title bar buttons.

2. The terminal

It's the heart of the simulator: this is where you type all your pentesting commands.

How to use it

- Type the command and press Enter.
- Basic navigation: ls, cd, cat, pwd, echo, etc. work like in real Linux.
- Browse your command history with the ↑/↓ arrow keys.
- You can use redirections (>, >>, <) and pipes (|), for example: cat file.txt | grep flag.

Settings

Each terminal has a settings menu (gear icon in the window bar) where you can change:

- Font size (from 10 to 20 px).
- Window opacity.
- Text color of the prompt.

Number of terminals

You can have up to 5 terminals open at the same time. Use the + button on the top bar or the Applications → Open Terminal menu.

Command help

Type help in any terminal to see the full list of available commands. You can also check a specific command:

```
help <command>
```

Important: it's a simulation This simulator does not implement every command of a real system, and the existing commands do not support all of their parameters (only the ones needed for the missions). The goal is educational: learn the flow of pentesting (enumeration → scanning → exploitation → post-exploitation), not the exhaustive syntax of each tool.

3. The browser

In web labs you'll find the Chrome icon on the desktop. The simulator's browser works like a real one:

- Address bar to type URLs (e.g.: `http://<ip>/login`).
- Simulated web pages that reproduce vulnerable applications (login, admin panels, WordPress blogs, directories with sensitive files, etc.).
- Navigation buttons (back / forward / reload) and tabs.

It's a complementary tool: many lab hints require looking at the website to find credentials, paths, or hidden features that you'll later use in the terminal.

4. Mission guide menu (Missions)

The right side panel shows the lab's mission list. Each mission represents a concrete step of the attack and has:

- The objective (enumeration, scanning, exploitation, etc.).
- A status bar: active / pending / completed.
- Hints: a button to reveal the next hint when you get stuck. There are up to 2 hints per mission.

The mission is completed automatically when you run the correct command (the simulator detects the action and validates the step). Follow the order of the missions to progress logically.

5. Network topology and enumeration

- Network map (network icon in the panel): shows the discovered machines and their status. As you progress, hosts detected with arp-scan, netdiscover, or nmap are added.
- Enumeration panel: records the results of your reconnaissance — open ports, detected services, found credentials, and confirmed vulnerabilities.

These panels are your "automatic notebook": you don't need to memorize IPs or credentials because the simulator stores them there as you discover them. Confirmed credentials are marked as VERIFIED when the service checks that they are valid.

6. Wallpapers and customization

From the Wallpapers icon (image icon) on the desktop or Applications → Change Wallpaper you can open the wallpaper picker. You can choose from several designs, and your choice is saved for the next time you open the simulator.

You can also customize the terminal (text color, opacity, and font size) from the settings menu of each window.

Enjoy the lab and happy hacking!
